

← Overview **Risk vs Benefit** HTE Validation Rollout Robustness →

Aggregate evidence
127 randomized villages

Compare village mean baseline risk with frozen out-of-village predicted intervention benefit signals

Baseline risk range

13.07%–23.31%

One mark per randomized village

Village mean predicted 10-year ASCVD risk

GRF benefit range

1.399–2.823 pp

Frozen out-of-village predictions

Simple HTE benefit range

1.147–3.277 pp

Frozen out-of-village predictions

GRF	Simple HTF
-----	------------

One mark per randomized village; n = 127.

Both signal views use the same fixed axes, so vertical position remains directly comparable when switching between GRF and Simple HTE.

Pairwise Spearman ρ

Comparison

9

•• GRF vs Simple HTE	0.4649
•• GRF vs Baseline Risk	0.4305
•• Simple HTE vs Baseline Risk	0.3349

- Higher baseline risk does not imply greater predicted intervention benefit.
- GRF and Simple HTE predicted intervention benefit signals are moderately correlated but not identical.
- Baseline risk and predicted intervention benefit are related but not interchangeable targeting signals.

- Each mark represents one randomized village cluster.
- Predicted intervention benefits are frozen out-of-village estimates measured in percentage points.
- Positive values indicate a larger predicted risk reduction.
- Correlations are village-level Spearman rank correlations.

Evaluate prioritization performance, calibration, and classical subgroup evidence

Spearman ρ ranges from -1 to 1; agreement does not establish superiority.

Income: annual household income (yuan). *Baseline risk: baseline predicted 10-year ASCVD risk; groups partially reconstructable. Descriptive full-data estimates; CI overlap is not an interaction test.

- AUTOC supports prioritization, not effect magnitude or policy value.
- Calibration near 1 does not establish superiority.
- Subgroup estimates are descriptive; CI overlap is not an interaction test.
- Baseline-risk groups are partially reconstructable.
- Endpoint: predicted risk, not observed cardiovascular events.
- Participant-score agreement is descriptive and does not validate individual treatment selection.
- Classical subgroup estimates are descriptive full-data results, not out-of-village prioritization validation.
